Energy Disputes Roadmap

Step 0.1 ⟶ 6 concepts —— i) Charge.
ii) Current.
iii) Voltage.
iv) Resistance.
v) Power
vi) Energy.

i) Charge ⟶ An property of a particle (attribute in its essence) which justifies the classification of particles, on account of certain reactions observed, into 2 classes —— positive & negative (also, positively charged particles are protons & negatively charged particles are electrons). The reactions observed are attraction & repulsion. One positively charged particle & One more positively charged particle experiences repulsion among themselves. Same reaction for negatively charged particles. One positive & One negative experiences attraction among themselves.
Furthermore, particles with neither a positive charge nor a negative charge are known as Neutrons (neutrally charged particle).
The standardised unit to measure charge is coulomb.

ii) Current ⟶ Simply the movement of charged particles. Such movement is a consequence of voltage & potential.
The standardised unit to measure current is ampere.

iii) Voltage ⟶ Potential difference that exists between the locations in the field, which causes the charged particles (hereinafter referred to as charge) to flow from a location of higher potential to a location of lower potential. It is the difference (the value), a consequence of comparison with respect to "higher" & "lower".

Potential itself is simply capacity. This relates to the capacity that a charge assumes on account of being in a location. This location itself is a term given to understand the space where the charges are existing, which causes such space to have meaning. Such capacity therefore is understood to be obtained on account of where the charge is located in such space, relative to, of course, the other charges.
The standardised unit to measure voltage is volt.

iv) Resistance ⟶ Current must flow through something. This something is termed as medium. This medium, on account of it having a certain order of its building blocks (its simplest, its path), offers a certain resistance in the path of the charges. It's like rocks that are on the path of a flowing stream. On account of such resistance being there, the capacity to cause change (energy) reduces, meaning it is subtracted from the charges' potential & therefore converts to another form (from resistance, heat), adding the subtracted value of energy to the other form.
The standardised unit to measure Resistance is ohm.

v) Power ⟶ In Resistance above mentioned, the element of obstruction itself is termed as Resistance. Such Resistance's consequence is the conversion (in form) of energy that takes place. Now, the process of conversion itself can, with respect to time, be understood as to consume or receive a certain time varying across different conversions. It is exactly this "how much time" question that power measures. Therefore, power is simply how much time is taken for energy to convert from one of its forms to another. The phrase "how much time" refers to the measurement of time itself with respect to the conversion of energy; although the measurement is really happening of the conversion process in ratio with a certain time.
The standardised unit to measure Power is watt.

vi) Energy ⟶ This term refers to the alleness to cause change. While this does inevitably bring in the conception of potential (capacity), it is more so associated with motion or change itself. This is classified into 2 classes —— Potential energy & Kinetic energy. Potential energy is effectively capacity of capacity to cause change, however, it is understood with reference to the conception of the location in the field, i.e. capacity to cause change by virtue of position. Kinetic energy, on the other hand, refers to the actual motion itself or the absence of rest. It is the actually "causing" of the change.
The standardised unit to measure Energy is joule.

The industry standard of understanding Power & Energy is with ratio to time. While Power remains the same, energy becomes the total time that Power has actually occurred. What I mean by this is, while Power is the rate of conversion of energy, the industry requires to understand how long energy has been converted for. Because, even the industry itself cannot create the energy that is to be sold, it holds energy in one form & then supplies it. That supplying, depending upon how long it has continued for, becomes how much energy has been used (in such converted form). Therefore, there is no measurement of energy itself, just the measurement of total continuation of conversion of energy. Such then becomes measured in the standardised unit of Wh (Watt-hour) i.e. rate of conversion of energy with a certain continuation of such.
